Problem 2

Colors in Java can be represented by objects of type ***Color***. Each such object contains the ***red***, ***green*** and ***blue*** components of the corresponding color as integer values from **0** to **255**. Consider below a Java code that creates and initializes a rectangular array of ***Color*** type:

```
import java.util.Scanner;
import java.awt.Color;

public class Colors {

public static void main(String args[]) {
      Scanner in = new Scanner(System.in);

// Read number of rows and columns and create a Color array of such size
      Color[][] c = new Color[in.nextInt()][in.nextInt()];

// For each element read the red, green and blue components as integers and
// create a Color object by calling Color(int, int, int) constructor
      for (int row = 0; row < c.length; row++)
            for (int col = 0; col < c[0].length; col++)
                  c[row][col] = new Color(in.nextInt(), in.nextInt(), in.nextInt());
// TO BE CONTINUED
}
}
```

Continue with a Java code that creates another array ***Color[][] g*** of the same size and fills it with gray equivalents of the colors from the array ***Color[][] c***. To get a grey equivalent of a given color ***c[i][j]***, it is enough to construct a ***Color*** object, whose red, green and blue components all are equal to the calculated average of red, green and blue components of the initial ***c[i][j]***. Use ***int getRed()***, ***int getGreen()*** and ***int getBlue()*** methods of class ***Color***.

```
Color [][] g = new Color[c.length][c[0].length];
for (int row=0; row<c.length; row++) {
    for (int col=0; col<c[0].length; col++)
{ int gray = (c[row][col].getRed() +
  c[row][col].getGreen() + c[row][col].getBlue())/3;
  g[row][col] = new Color[gray, gray, gray]);
}
}
```
