#### Problem 1

The easiest way to implement rotation by  $90^{\circ}$  of a square array is to transpose it and then reverse all its rows separately. Transposing once more after the rotation will result in vertical flip the top row will appear at the bottom, the second row will become the last but one, etc. Write a C++ function void flip(int \*a2D, int size) that takes as its argument a pointer to the first element of a square array int \*a2D of the specified int size and flips it vertically. Use already implemented functions void reverse(int a1D[], int length) and void transpose(int \*a2D, int size):

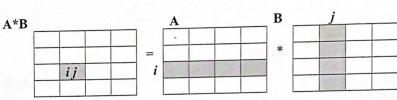

```
void reverse(int alD[], int length)
        for (int i = 0; i < length / 2; i++)</pre>
                swap(alD[i], alD[length - 1 - i]);
void transpose(int *a2D, int size)
        for (int row = 0; row < size; row++)</pre>
                for (int col = row + 1; col < size; col++)</pre>
                       swap(a2D[row * size + col], a2D[col * size + row]);
void flip (int *adD, int size){
      transpose ({a2P, size);
forlint i=0, i<size, 0++) {
    tenerse ({a2D[0], size);
    transpose ({a2P, size);
}
```

### Problem 2

Using functions transpose() from Problem 1 and scalar() from below, write a C++ function void mult(int \*a2D, int \*b2D, int \*product, int size) that takes as its arguments pointers to the first elements of square arrays int \*a2D and int \*b2D of the same specified int size, computes their product and saves it in another square array of the same size, the pointer to the first element of which is given by int \*product. Each element  $p_{ij}$  in the  $i^{th}$  row and  $j^{th}$  column of the array \*product is the scalar product of the  $i^{th}$  row of \*a2D and  $j^{th}$  column of \*b2D and is calculated by the

expression:  $p_{ij} = \sum_{k=0}^{size-1} a_{ik} b_{kj}$ int scalar(int a[], int b[], int length) int result = 0; for (int i = 0; i < length; i++)</pre> result += a[i] \* b[i]; return result;

roid multlint \*a2P, int \* B3D, it \* product, int size)[ transpose (BDD, size);
for (int [=0, ic size, i++) {
for (int f=0, jc size, j++) {

product [i][j]: scorlar[a2P[i], B2P[j]);

transpose (bes, size);

OOP. MT2-240315-10110

Problem 3 Using, if you wish, segment() and rotate() functions from the C++ Reference Functions section, write a C++ function void spiral2(int \*a2D, int even\_size) that takes as its argument a pointer to the first element of a square array int \*a2D of the specified even size int even\_size and fills its top-left and bottom-right quadrants with spirals of successive values from 1 to even\_size2/4 . The remaining two quadrants are filled with zeros. Each spiral propagates horizontally toward the array center, then vertically toward the center, then in opposite directions horizontally and vertically, and so on. Obviously, the spirals do not cross the central axes. A shaded example is

```
shown below:
int* segment(int *start, int length, int direction, int increment)
      for (; length > 0; length--)
            *(start + direction) = *start + increment;
            start += direction;
      return start;
```

void spiral2(int\*a2P), int even-size){
forl(int i=0, i<even-size, i+r){ faliat 5=0, se even-site, 5++)[ \* a & D [ & ] [ 5] = O.

g Jee Problem 2

	1	2	3	0	0	0
	8	9	4	0	0	0
	7	6	5	0	0	0
1	0	0	0	5	6	7
l	0	0	0	4	9	8
İ	0	0	0	3	2	1

segment: even-site + even-site./4.;

segment:

segment (2000)

segment (2000)

segment (2000)

lower-site /4+5][even-site /4+5][even-site /4+1],

even-site + even-site +4+5]

even-site + even-site +4+5];

Forlint 5=0, Sc even-siteld, S++) {.

Segment (le 8 02D[even-site/4+1][even-site/4], even-site/2, 1,

even size \*\* even-site/4);

Too few explicit calls of segment()
