### Problem 1

Square arrays can be rotated by 900, say, in clock-wise direction. For example:

1	2	3	4	5
6	7	8	9	10
11	12	13	14	15
16	17	18	19	20
21	22	23	24	25

	21	16	11	6	1
	22	17	12	7	2
>	23	18	13	8	3
	24	19	14	9	4
	25	20	15	10	5

13/18

The easiest way to implement the rotation by 90° is to transpose the initial square array and then to reverse all its rows separately. Write a Java method *void rotate(int[][] array2D)* that takes as its argument a square *int[][] array2D* and rotates its. Use already implemented methods *void reverse(int[] array1D)* and *void transpose(int[][] array2D)*:

# Problem 2

Colors in Java can be represented by objects of type *Color*. Each such object contains the *red*, *green* and *blue* components of the corresponding color as integer values from 0 to 255. Consider below a Java code that creates and initializes a rectangular array of *Color* type:

```
Color [J[] g = new Color [C length ] [ CEOS. length ];

for (int row = 0; row < g. length; row ++) {

for (int col = 0; col < gEOS. length; col ++) {

int average = (cErow JEcol J. getRed 1) + CErow SEcol J. get Green 1) + CErow JEcol J. getBlue() };

g [ row J [ col ] = new Color (average, average, average);

}
```

#### Problem 3

Similar to files, strings also can be related to streams in C++, this time using *stringstream* objects. Particularly, it is enough to create an object of type *istringstream* to organize formatted reading from a string. Consider, for example, a C++ code below:

```
#include <string>
#include <sstream>
#include <iostream>
using namespace std;

void main()
{
    string text = "Before increment: 199999999", word;
    int num;
    istringstream tokens(text);

    tokens >> word >> num;
    cout << "After " << word.substr(7) << num + 1 << endl;
}
// After increment:2000000000</pre>
```

Write a C++ function *double value(string expression)* that takes as its argument a string representing an arithmetic expression, evaluates it and returns its value. The expression includes only '+' and '-' operations and double operands, both positive and negative. The operands and operations are delimited by spaces.

For example, value("5.1 - -0.7 + 1.2") results in 7.0.

```
double value (string expression) {
  istring stream tokens (expression);
  string word;
  double num, next num;
  tokens >> num;
  double result = num;
  while (tokens >> word) {
    tokens >> next num;
  if (word == "+")
    Tesult += rext num;
  else
    vesult -= next num;
  }
  return result;
}
```
